

Structural Material

Powder Metallurgy – Hot Isostatic Pressing of Steels in Support of Microreactors

6 March 2024

Tate Patterson

Welding Engineer, Idaho National Laboratory

Background

- Powder metallurgy hot isostatic pressing (PM-HIP) is a manufacturing method that produces components by consolidating metal powder
 - Minimizes additional fabrication steps
 - Eliminates solidification structures
 - Eliminates directional grain elongation caused by rolling or forging

MTC Powder Solutions

UK - Nuclear Advanced Manufacturing Research Center (UK-NAMRC) System

PM-HIP Adoption for Microreactors

- PM-HIP may benefit structural components for microreactors (i.e., core barrels, primary coolant loops, etc.) by reducing construction time, reducing waste, and improving component availability

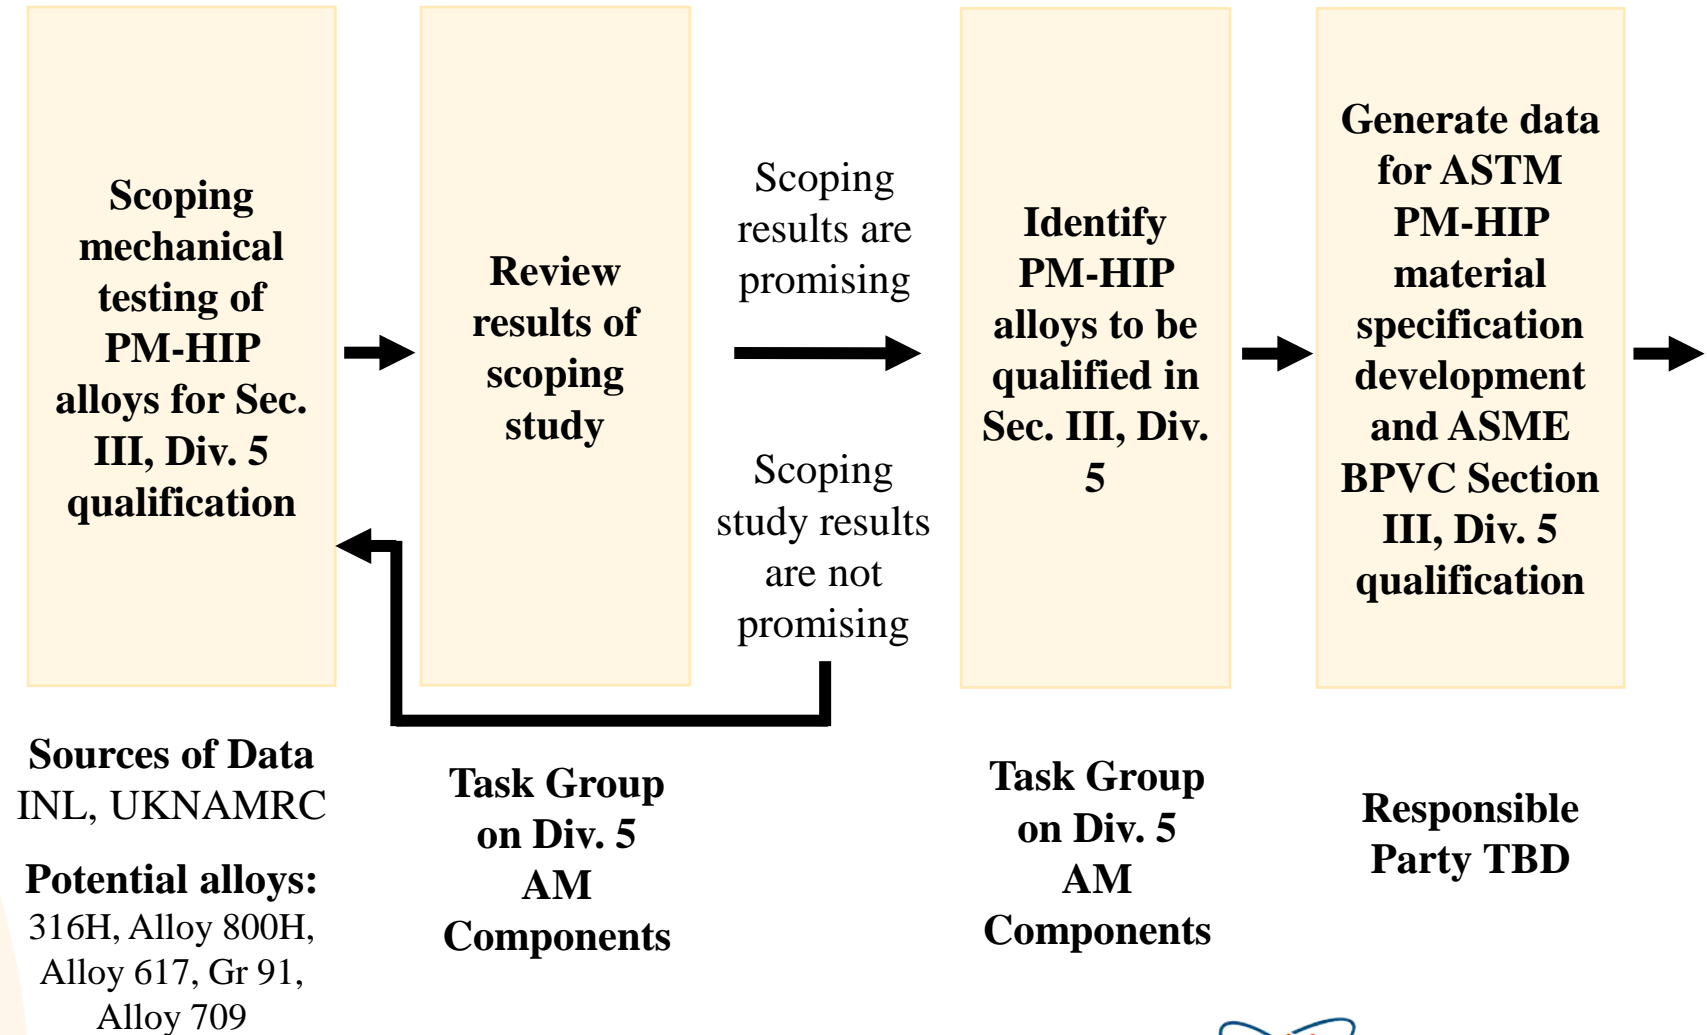

Goals

- Demonstrate high temperature mechanical properties of PM-HIP compared to wrought materials for Sec. III Div. 5 structural alloys
- Address PM-HIP 316 stainless steels to support multiple advanced reactors
- Develop specifications and acceptance criteria for PM-HIP components
 - Low temperature code case (up to 371°C)
 - High temperature code case (371°C < T < 816°C)

MARVEL Microreactor
Components

PM-HIP Div. 5 Code Case Roadmap

PM-HIP Div. 5 Code Case Roadmap

Submit data package to ASTM for alloy(s) to be added to ASTM PM-HIP

(Note: This step is not required for Gr. 91)

Responsible Party TBD

Determine ASME BPVC qualification approach

- 1) Use the same design rules (shortest)
- 2) Use a knockdown factor
- 3) Develop different design rules (longest)

Task Group on Div. 5 AM Components

Ballot code case for low temperature Sec. III, Div. 5 applications

Task Group on Div. 5 AM Components

Ballot code case for elevated temperature Sec. III, Div. 5 applications

Responsible Party TBD

Conclusions

- PM-HIP 316 stainless steels continued to show reduced cycles to failure under creep-fatigue testing conditions compared to wrought 316 stainless steel
- Grain boundary oxides are likely resulting in reduced creep-fatigue resistance through crack nucleation and propagation
 - Microstructure showed grain boundary cavitation ahead of the main crack
- Low cycle fatigue specimens showed transgranular and intergranular crack propagation
- Creep-fatigue specimens only showed intergranular crack nucleation/propagation

Future Work

- Conduct elevated temperature mechanical testing on 316H with low oxygen and processed using different hot isostatic pressing conditions
 - One-third of the powder was hot isostatically pressed and underwent a heat treatment identical to MTC Billet 1
 - Another third is being heat treated at different conditions to try to influence the oxide size/distribution
